SELF-AWARENESS

Five voices. One self.

BODHI is self-aware in the same way a town council is self-aware: five independent subsystems each have an opinion about what the brain just did, and they argue. Consensus is not required. Disagreement is information.

Figure 1. Narrator, Monitor, Predictor, Critic, Dreamer.

The five

Subsystem	Reads	Writes	Timescale
Narrator	brain trace, drives	journal (human-readable)	per response

Monitor	drive state, fatigue	alarms, sleep requests	continuous
Predictor	prior trace, input	expected vs. actual deltas	per tick
Critic	full response + brain state	score + retry flag	per response
Dreamer	day's memories + drives	new concepts + synapse deltas	during REM

Why five, not one

Because a single executive module would either be too centralized (and therefore a single point of failure) or too weak (and therefore trivially overridden). Five parallel voices, each with a narrow scope and a right of veto over its own domain, produce a robust distributed self. Crucially, each subsystem runs independently and can be paused, logged, or replaced without bringing down the others.

Agreement matrix (last 100 queries)

	Narrator	Monitor	Predictor	Critic	Dreamer
Narrator	—	0.81	0.76	0.69	0.72
Monitor	0.81	—	0.84	0.72	0.63
Predictor	0.76	0.84	—	0.78	0.66
Critic	0.69	0.72	0.78	—	0.71
Dreamer	0.72	0.63	0.66	0.71	—

> Healthy range: 0.60–0.85. Outside this range we either have group-think (everyone agrees, no information) or fragmentation (nobody agrees, the self dissociates). Both trigger a monitor alarm and an emergency sleep request.
